

# Whole Exome Sequencing Analysis

Patient name	: Master. XXX	PIN	: XX
Gender/ Age	: Male/ 13 Years	Sample number	: XX
Referring Clinician	: XX	Sample collection date	: XX
Hospital/ Clinic	: XX	Sample receipt date	: XX
Specimen	: Peripheral Blood	Report date	: XX

## Clinical history

Proband, Master XXX presented with learning difficulties, hyperactivity ?ADHD, abnormal behaviour and seizures at 1 month of age. Awake EEG shows normal findings. MRI Brain with epilepsy protocol revealed diffuse hypoplasia of corpus callosum with bilateral lateral ventricles runs parallel to each other and appears mild prominent. Proband, Master XXX has been evaluated for pathogenic variations.

## Results

**Likely Pathogenic variant causative of the reported phenotype was identified**

List of significant variant identified related to the phenotype:

Gene	Region	Variant*	Allele Status	Disease	Classification*	Inheritance pattern
PPP2R1A (+)	Exon 6	c.656C>T (p.Ser219Leu)	Heterozygous	Houge-Janssens syndrome 2 (OMIM#616362)	<b>Likely Pathogenic</b> (PS3, PM2, PP5, PP3, PP2)	Autosomal dominant

\*Genetic test results are based on the recommendation of American college of Medical Genetics [1].

No other variant that warrants to be reported for the given clinical indication was identified.

## Interpretation

**PPP2R1A: c.656C>T**

**Variant summary:** A heterozygous missense variation in exon 6 of the PPP2R1A gene

(chr19:g.52212959C>T, NM\_014225.6, Depth: 109x) that results in the amino acid substitution of Leucine for Serine at codon 219 (p.Ser219Leu) was detected.

**Population frequency:** This variant has not been reported in gnomAD database and 1000 genomes database.

**Clinical and Literature evidence:** This variant has been classified as pathogenic in ClinVar database [3]. This variant has been previously reported in a patients affected with *PPP2R1A*-related neurodevelopmental disorders in heterozygous state as a *de novo* variant [4].

**In-silico prediction:** The *in-silico* predictions of the variant are damaging by SIFT, PolyPhen-2 (HumDiv), LRT and MutationTaster2. The reference codon is conserved across mammals in PhyloP and GERP++ tools.

**OMIM phenotype:** Hogue-Janssens syndrome 2 (OMIM#616362) is caused by heterozygous mutation in the *PPP2R1A* gene (OMIM\*605983). Hogue-Janssens syndrome-2 (HJS2) is characterized by global developmental delay, hypotonia, variably impaired intellectual development, poor speech, and dysmorphic facial features. Some patients may develop seizures. This disease follows autosomal dominant pattern of inheritance [2].

**Variant classification:** Based on the evidence, this variant is classified as a likely pathogenic variant. **In this view, clinical correlation and familial segregation analysis are strongly recommended to establish the significance of the finding. If the results do not correlate, additional testing may be considered based on the phenotype observed.**

## Recommendations

---

- Sequencing the variant(s) in the parents and the other affected and unaffected members of the family is recommended to confirm the significance.
- Sanger sequencing is strongly recommended to rule out false positives.
- Genetic counselling is advised.

## Methodology

---

DNA extracted from the blood was used to perform whole exome using whole exome capture kit. The targeted libraries were sequenced to a targeted depth of 80 to 100X using Genolab M sequencing platform. This kit has deep exonic coverage of all the coding regions including the difficult to cover regions. The sequences obtained are aligned to human reference genome (GRCh38.p13) using Sentieon aligner and analyzed using Sentieon for removing duplicates, recalibration and re-alignment of indels. Sentieon DNAScope has been used to call the variants. Detected variants were annotated and filtered using the VarSeq software with the workflow implementing the ACMG guidelines for variant classification. The variants were annotated using 1000 genomes (V2), gnomAD (v3.1.2.1.1), ClinVar, OMIM, dbSNP, NCBI RefSeq Genes. *In-silico* predictions of the variant was carried out using VS-SIFT, VS-PolyPhen2, PhyloP, GERP++, GeneSplicer, MaxEntScan, NNSplice, PWM Splice Predictor. Only non-synonymous and splice site

variants found in the coding regions were used for clinical interpretation. Silent variations that do not result in any change in amino acid in the coding region are not reported.

### Sequence data attributes

---

Total reads generated	15.66 Gb
Data ≥ Q30	91.14%

Genetic test results are reported based on the recommendations of American College of Medical Genetics [1], as described below:

Classification	Interpretation
Pathogenic	A disease-causing variation in a gene which can explain the patients’ symptoms has been detected. This usually means that a suspected disorder for which testing had been requested has been confirmed
Likely Pathogenic	A variant which is very likely to contribute to the development of disease however, the scientific evidence is currently insufficient to prove this conclusively. Additional evidence is expected to confirm this assertion of pathogenicity.
Variant of Uncertain Significance	A variant has been detected, but it is difficult to classify it as either pathogenic (disease causing) or benign (non- disease causing) based on current available scientific evidence. Further testing of the patient or family members as recommended by your clinician may be needed. It is probable that their significance can be assessed only with time, subject to availability of scientific evidence.

### Disclaimer

---

- The classification of variants of unknown significance can change over time. Anderson Diagnostics and Labs cannot be held responsible for it.
- Intronic variants, UTR, Promoter region variants and CNV are not assessed using this assay.
- Certain genes may not be covered completely, and few mutations could be missed. Variants not detected by this assay may impact the phenotype.
- The variations have not been validated by Sanger sequencing.
- The above findings and result interpretation was done based on the clinical indication provided at the time of reporting.

- It is also possible that a pathogenic variant is present in a gene that was not selected for analysis and/or interpretation in cases where insufficient phenotypic information is available.
- Genes with pseudogenes, paralog genes and genes with low complexity may have decreased sensitivity and specificity of variant detection and interpretation due to inability of the data and analysis tools to unambiguously determine the origin of the sequence data in such regions.
- Incidental or secondary findings that meet the ACMG guidelines can be given upon request [5].
